# Future Fuel Cycle Options

## Domestic Fuel Cycle Options

Title	Description	Challenges
Open	Once Through Current US PWR Fleet No Separations No Recycling Higher Burnups	High Temperatures, Volumes
Modified Open	Partial Recycling Next Gen. PWR Fleet Limited Separations Limited Transmutation Advanced Fuel Forms HLW treatment	Both high volumes and myriad fuel streams
Closed	Full Recycling Full Separations Full Recycling VHTGR, SFRs, other transmutation HLW treatment	Myriad fuel streams

Table: Domestic Fuel Cycle Options

## Methodology : Modularity

A modular repository framework facilitates

- interchangeable subcomponents (i.e. buffer material) so that the impact on the disposal system performance may be observed
- and simulations with varying levels of detail.

## Methodology : Modularity

A modular repository framework facilitates

- interchangeable subcomponents (i.e. buffer material) so that the impact on the disposal system performance may be observed
- and simulations with varying levels of detail.

Integration with a fuel cycle simulator facilitates

- analysis of feedback effects upon the fuel cycle
- and investigation of fuel cycle choices on disposal system performance.

## Methodology : Abstraction for Efficiency

Abstraction simplifies models while capturing salient physics. Parametric analysis with detailed models will inform simpler models at the level of detail important for fuel cycle analysis.

Summary

## Top Level Fuel Cycle Simulators

**Figure:** Top level simulators are intended to model the collective behavior of various fuel cycle decisions and strategies [?].

## Need For an Integrated Repository Model

Current fuel cycle simulators neglect disposal system decisions and repository behavior. Most report masses and mass indexed metrics such as radiotoxicity, both meaningless without release pathway analysis and not informative for disposal system options.

**Repository Capabilities within Systems Analysis Tools**

Tool	Institution	Fuel Disposition	Radionuclide Transport	Heat Transport
NUWASTE [?]	NWTRB	yes	no	no
VISION [?]	INL	yes	no	YMR only

## Radionuclide Transport

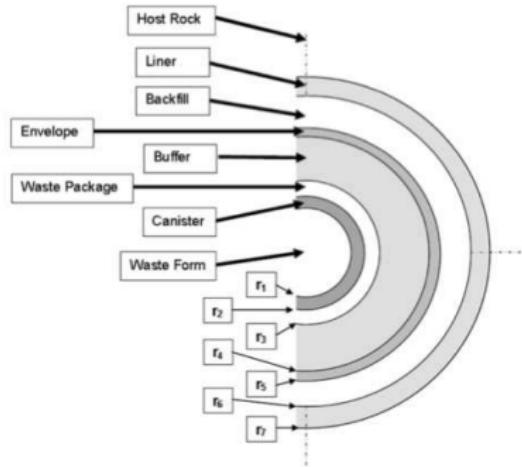

Figure: After waste package failure, radionuclides pass through successive layers of the engineered barrier system [?].

- Source Term - Radionuclide mass flux to the environment
  - Safety and Risk Metric
  - EPA Regulation
- Radionuclide transport is a function of
  - Geochemistry - chemically induced material degradation, radionuclide solubility limits, sorption, colloid mobility, etc.
  - Hydrology - water induced material degradation, water movement through pores and fractures, dissolved contaminant dispersion.
  - Thermal Effects - thermally induced material degradation, thermal hydrological effects.

## Waste Form Release Models

### Waste Form Types

WF Type	SubTypes	Contents	Release Drivers
Once Through	CSNF Ceramic Oxide CSNF Ceramic Oxide HTGR TRISO Graphite DSNF Metal DSNF Carbides DSNF Ceramic Oxides	Nominal BU UOx & MOX High BU UOx & MOX High BU High BU N Reactor Fuel Fast Reactor Fuels Research Reactor Fuels	redox rxns redox rxns, heat graphite rxns metal rxns, heat carbide rxns, heat redox rxns, heat
Borosilicate Glass	Current Future	MA, Cs/Sr Mo, no MA no Cs/Sr	heat, alteration alteration
Glass Ceramic	Glass Bonded Sodalite	Echem treated UOx, MOX	redox, alteration
Metal Alloy	From Echem From Aqueous	Cladding, noble metals transition metals	metal rxns, heat metal rxns, heat
Advanced Ceramic		volatized iodine	ceramic rxns, redox
Salt	Cementitious Sodium	separated streams	alkaline rxns, dissolution

**Table:** An array of waste forms developed for nuclear wastes will have a corresponding array of dominant release mechanisms [?]

## Waste Package Failure Models

Waste package failure can, in general, be represented with an expression of the number of failed waste packages,  $n_F$  failing per unit time. This is a simple product between the initial number of waste packages,  $N$ , and the rate,  $f$ , of failure,

$$n_F = N \cdot f(). \quad (1)$$

This rate may be a physical function,

$$f() = N \cdot f(t, T, \dots). \quad (2)$$

or any time dependent function,

$$f() = f(t). \quad (3)$$

of which instantaneous failure is a special case,

$$f() = \delta(t - t_F). \quad (4)$$

as is the Weibull distribution,

$$f(t, \lambda, k) = \begin{cases} \frac{k}{\lambda} \left( \frac{t}{\lambda} \right)^{k-1} e^{-(t/\lambda)^k} & t \geq 0, \\ 0 & t < 0. \end{cases} \quad (5)$$

## Waste Package Failure Models

**Current Waste Package Failure Models**

Model	WP Failure Mode	Details
TSP	Physical WAPDEG Model	$t_{delay} = 300,000$ years
Ahn 2003	Instantaneous Failure	$t = 0$
Ahn 2007	Instantaneouw Failure	$T_f = 75,000$ years
Li	Physical WAPDEG model	$t_{delay} = 300,000$ years
Hedin 2003	Instantaneous Failure	$t_{delay} = 300$ years
UFD 2011	Instantaneous Failure	$t = 0$

**Table:** The above represent some current methods by which waste package failure rates are modeled.

## Solute Transport in Permeable Porous Media

$$\frac{\partial nC}{\partial t} = -\nabla \cdot (F_c + F_{dc} + F_d) + m \quad (6)$$

where

$n$  = solute accessible porosity [%]

$m$  = solute source [ $kg \cdot m^{-3} \cdot s^{-1}$ ].

$C$  = concentration [ $kg \cdot m^{-3}$ ]

$v$  = pore velocity [ $m \cdot s^{-1}$ ]

$t$  = time [s]

$\alpha$  = dispersivity [m]

$F_c$  = advective transport [ $kg \cdot m^{-2} \cdot s^{-1}$ ]

$D_e$  = effective diffusion coefficient [ $m^2 \cdot s^{-1}$ ]

$$= nvC$$

$F_{dc}$  = dispersive transport [ $kg \cdot m^{-2} \cdot s^{-1}$ ]

$$= \alpha nv \nabla C$$

and

$n \cdot v$  = Darcy velocity [ $m \cdot s^{-1}$ ]. (7)

$F_d$  = diffusive transport [ $kg \cdot m^{-2} \cdot s^{-1}$ ]

$$= D_e \nabla C$$

## Dispersion

It is customary to define the combination of molecular diffusion,  $D_e$  and mechanical dispersion,  $\alpha v$ , as  $D$

$$D = \alpha v + D_e \quad (8)$$

such that the mass conservation equation becomes:

$$\frac{\partial(nC)}{\partial t} = \nabla(nD\nabla C) - \nabla(nvC) \quad (9)$$

Adding sorption, by accounting for a change in mass storage,

$$\frac{\partial(nC)}{\partial t} + \frac{\partial(s\rho_b)}{\partial t} = \nabla(nD\nabla C) - \nabla(nvC) \quad (10)$$

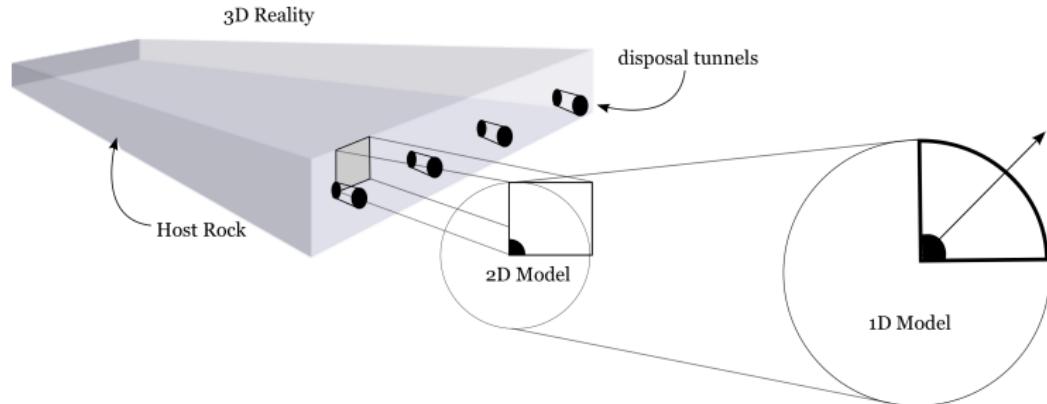

where

$s$  = sorption coefficient

$\rho_b$  = bulk (dry) density [ $kg/m^3$ ].

## Dimensionality

**Figure:** Employing the symmetries of the disposal layout can enable lower dimensional models.

## Dispersion

For unidirectional flow, the unidirectional dispersion tensor gives

$$D_x \frac{\partial^2 C}{\partial x^2} + D_y \frac{\partial^2 C}{\partial y^2} + D_z \frac{\partial^2 C}{\partial z^2} + v_x \frac{\partial C}{\partial x} = R_f \frac{\partial(nC)}{\partial t}. \quad (11)$$

## Diffusion

A special case of uniform flow, no flow, simplifies to the diffusion equation,

$$D_x \frac{\partial^2 C}{\partial x^2} + D_y \frac{\partial^2 C}{\partial y^2} + D_z \frac{\partial^2 C}{\partial z^2} + = R_f \frac{\partial(nC)}{\partial t}. \quad (12)$$

## Precipitation

Elemental solubility limits are based on the maximum concentration of an element which can exist in solution.

This limitation can be implemented at the release surfaces by placing a hard cap on released mass  $m$  concentration,

$$m_{1i}(t) \leq v_{1i}(t)C_{sol} \quad (13)$$

where

$m_{1i}$  = dissolved kg of radionuclide i

$v_{1i}$  = void volume

$C_{sol}$  = solubility limit

## Sorption

If it is assumed that sorption can be approximated as a linear equilibrium, reversible reaction,

$$\frac{\partial(s\rho_b)}{\partial t} = (R_f - 1) \frac{\partial(nC)}{\partial t} \quad (14)$$

equation (10) becomes

$$\nabla(nD\nabla C) - \nabla(nv) = R_f \frac{\partial(nC)}{\partial t} \quad (15)$$

where

$R_f$  = retardation factor

$$= 1 + \frac{\rho_b K_d}{n} \quad (16)$$

$\rho_b$  = bulk density of the rock matrix

and

$K_d$  = species distribution coefficient.

## One Dimensional Solution with a Constant Concentration Source

An analytical solution for the one dimensional case with a continuous source of constant concentration is known [?]. For the boundary conditions

$$C(0, t) = C_0 \quad (17)$$

and

$$\left. \frac{\partial C}{\partial x} \right|_{x=\infty} = 0 \quad (18)$$

as well as the initial condition

$$C(x, 0) = 0 \text{ for } x \in (0, \infty), \quad (19)$$

the so called Ogata and Banks solution gives

$$C(x, t) = \frac{C_0}{2} \left[ \operatorname{erfc} \left( \frac{x - \frac{v_x t}{R_f}}{2\sqrt{\frac{D_x t}{R_f}}} \right) + e^{\frac{v_x x}{D_x}} \operatorname{erfc} \left( \frac{x + \frac{v_x t}{R_f}}{2\sqrt{\frac{D_x t}{R_f}}} \right) \right]. \quad (20)$$

where

$$\operatorname{erfc}(x) = \frac{2}{\sqrt{\pi}} \int_x^\infty e^{-t^2} dt. \quad (21)$$

## Heat Limits In Geology

Important heat limits in materials of the repository restrict loading designs and capacity.

**Thermal Behavior of Various Concepts**

Feature	Clay	Granite	Salt	Deep Borehole
Buffer Limit [°C]	100 (Fo-Ca)	100 (Fo-Ca)	180	100 (Fo-Ca)
Host Limit [°C]	100 (alteration)	200 (cracking)	180 (brines)	none
Conductivity [ $\frac{W}{m \cdot K}$ ]	1 – 2	2 – 4	~ 4	2 – 4
Coalescence	yes	no	yes	no

# Impact of Repository Designs

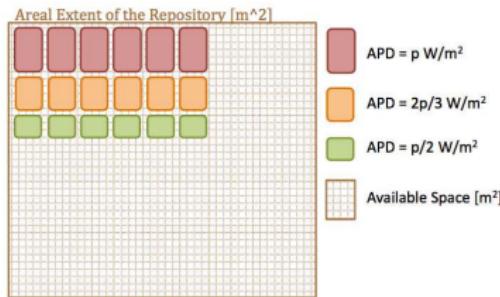

**Yucca Mountain Footprint Expansion Calculations**

Author	Max. Capacity <i>tonnes</i>	Footprint <i>km</i> <sup>2</sup>	Details

**Table:** Various analyses based on heat load limited repository designs have resulted in footprint expansion calculations of the YMR.

## Heat Based Capacity

**Figure:** Areal Power Density (APD) can be used to determine appropriate repository loading for arbitrary waste streams.

Loading is subject to the constraints,

$$P_{\text{tot}} \leq P_{\max} \quad (22)$$

$$APD_i \leq APD_{\max} \quad (23)$$

where

$$P_{\max} = A \cdot APD_{\max} \quad (24)$$

$$P_{\text{tot}} = \sum_{i=0}^N n_i P_i \quad (25)$$

$P_i$  = power of package i

$n_i$  = ith package

$N$  = number of packages

$APD_{\max}$  = max areal power density

## Detailed Techniques

Models of Heat Load for Various Geologies

Source (Who)	Nation (Where)	Geology (What)	Methodology (How)
Enresa [?]	Spain	Granite	CODE_BRIGHT 3D Finite Element
NRI [?]	Czech Rep.	Granite	Specific Temperature Integral
ANDRA [?]	France	Granite	3D Finite Element CGM code
SKB [?]	Sweden	metagranite	1D-3D Site Descriptive Models
SCK-CEN [?]	Belgium	Clay	Specific Temperature Integral
ANDRA [?]	France	Argile Clay	3D Finite Element CGM code
NAGRA [?, ?]	Switzerland	Opalinus Clay	3D Finite Element CGM code
GRS [?]	Germany	Salt	HEATING (3D finite difference)
NCSU(Li) [?]	USA	Yucca Tuff	Specific Temperature Integral
NCSU(Nicholson) [?]	USA	Yucca Tuff	COSMOL 3D Finite Element
Radel & Wilson [?]	USA	Yucca Tuff	Specific Temperature Change

Table: Methods by which to calculate heat load are independent of geology.  
Maximum heat load constraints, however, vary among host formations.

Similar heat transport models can be used for all geologies, but are differentiated by material parameters ( $c_p, K, \rho$ ) and different thermal constraints.

## ANL model

A model created by the UFD team at Argonne national lab using the SINDA\G heat transport framework employs a lumped parameter model and an optimization loop to arrive at a minimal drift spacing for a given waste stream in agreement with user input thermal limits.

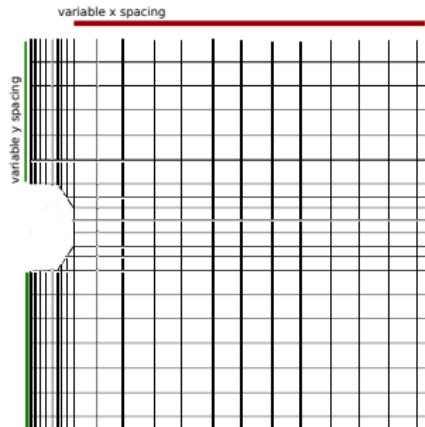

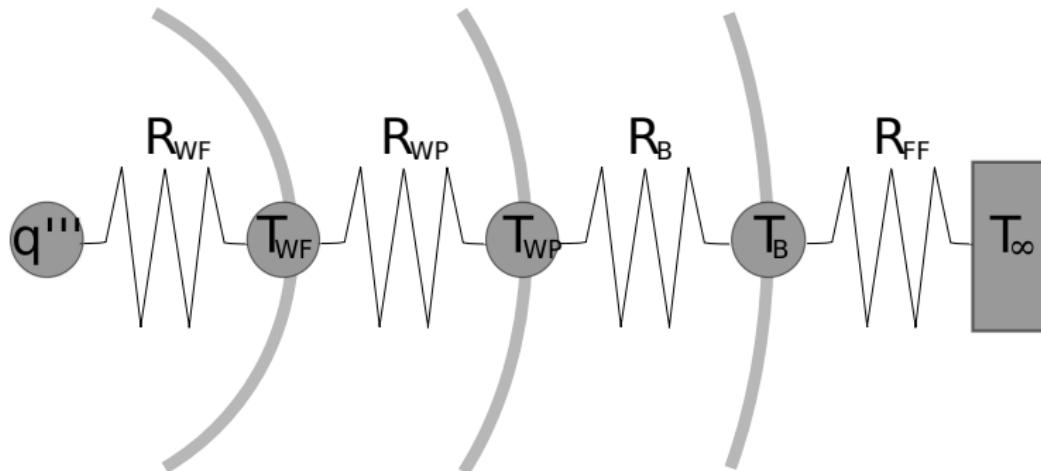

Figure: Two adjustable geometric dimensions of the ANL model [?].

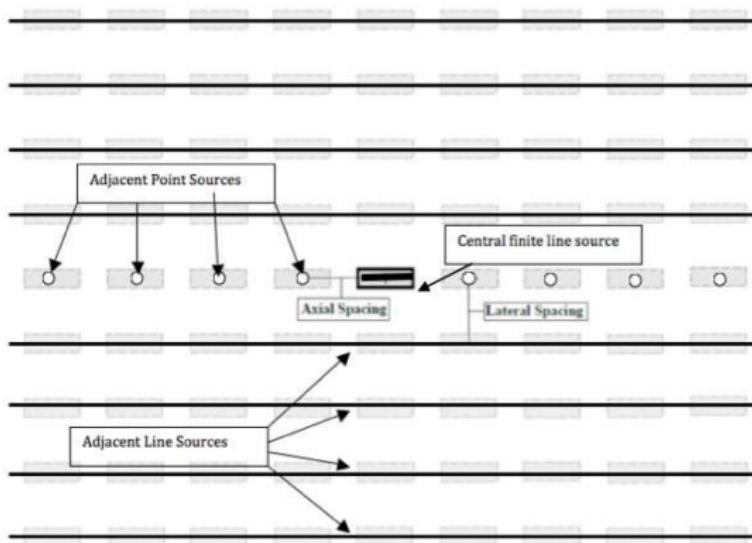

## Lumped Parameter Technique

**Figure:** The lumped parameter analogy used for heat transfer can be applied to the one dimensional approximation to the disposal system concept.

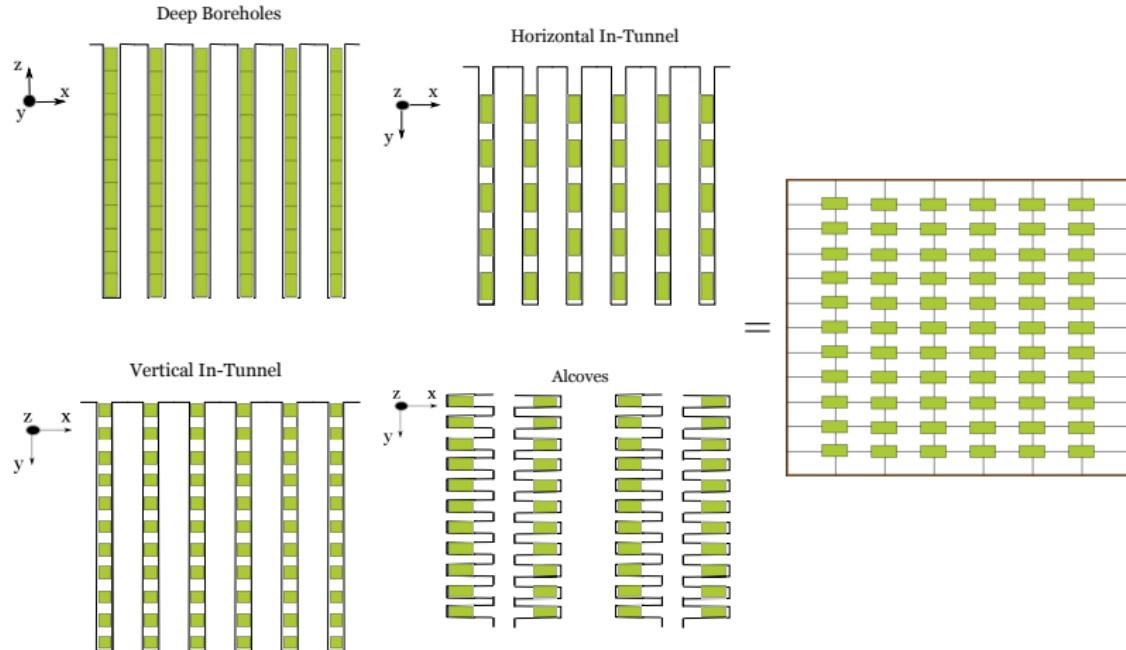

## LLNL Model : Geometry

**Figure:** Vertical, horizontal, alcove, and borehole emplacement layouts can be represented by a line of point sources and adjacent line sources [?].

# Repository Layouts

## LLNL Model : Solution Strategy

A MathCAD solution of the transient homogeneous conduction equation,

$$\nabla^2 T = \frac{1}{\alpha} \frac{\partial T}{\partial t}. \quad (26)$$

Superimposed point and line source solutions approximate the repository layout. The solution of this equation at the boundary of the EBS and the waste package is then treated as a boundary condition for the heterogeneous steady state equation,

$$\dot{q} = UA_{out} (T_{in} - T_{out}) \quad (27)$$

where

$$U = \frac{1}{\sum_i R_i} \quad (28)$$

which, for the detailed EBS becomes

$$U = \frac{1}{R_{WF} + R_{WP} + R_{buffer} + \dots} \quad (29)$$

which calculates a resulting temperature gradient through the geometry at each point in time for each layer surface, assuming an infinite line source [?].

## Cyclus Modular Architecture and Open Development

The combination of modular encapsulation within the software architecture and an open development paradigm allows for simulation at multiple levels of simulation detail.

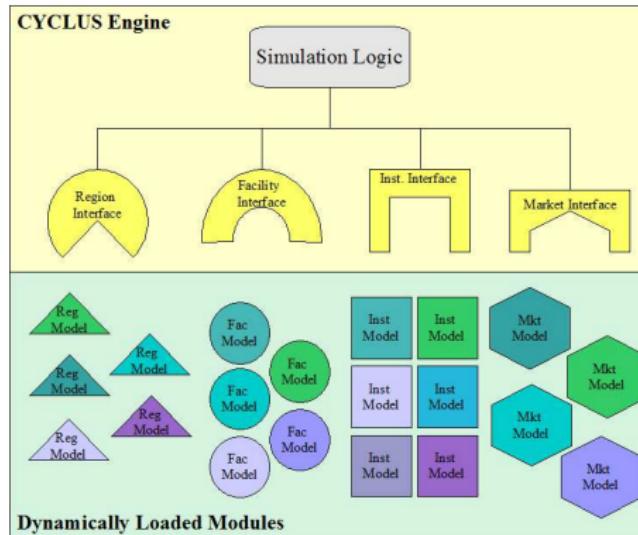

## Encapsulation

**Figure:** Regions, Institutions, Facilities, and Markets are all black boxes.

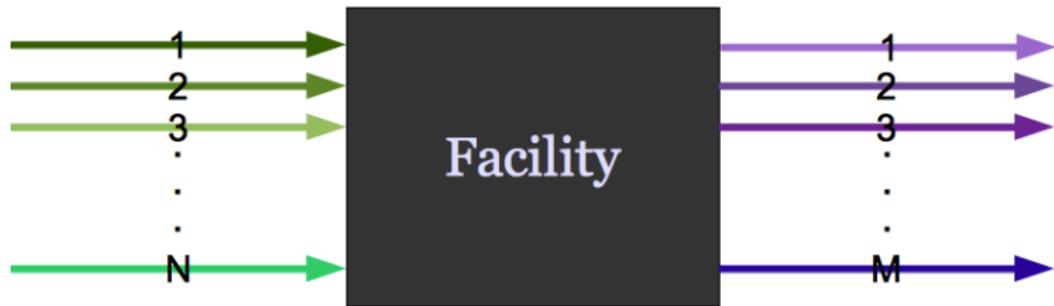

## Module Interfaces

**Figure:** Well defined model interfaces facilitate model interchange. The user may choose the model at their desired level of detail.

## Facilities Are Black Boxes

**Figure:** Each facility in the simulation makes requests and offers to fill its stocks and empty its inventory respectively.

## Facilities Are Black Boxes

Figure: A facility might only make offers.

## Facilities Are Black Boxes

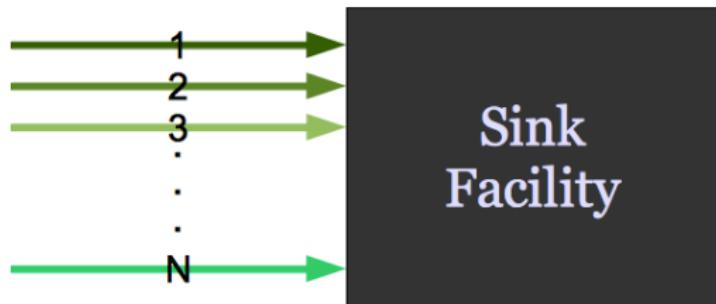

Figure: A facility might only make requests.

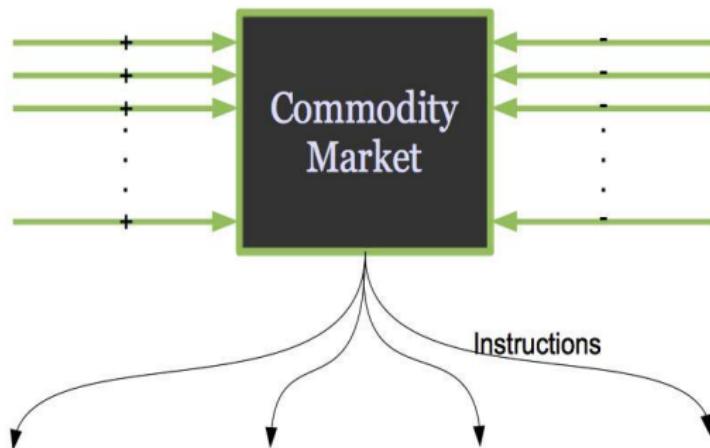

## Each Commodity is Associated with a Market

Figure: A market receives offers and requests concerning its commodity.

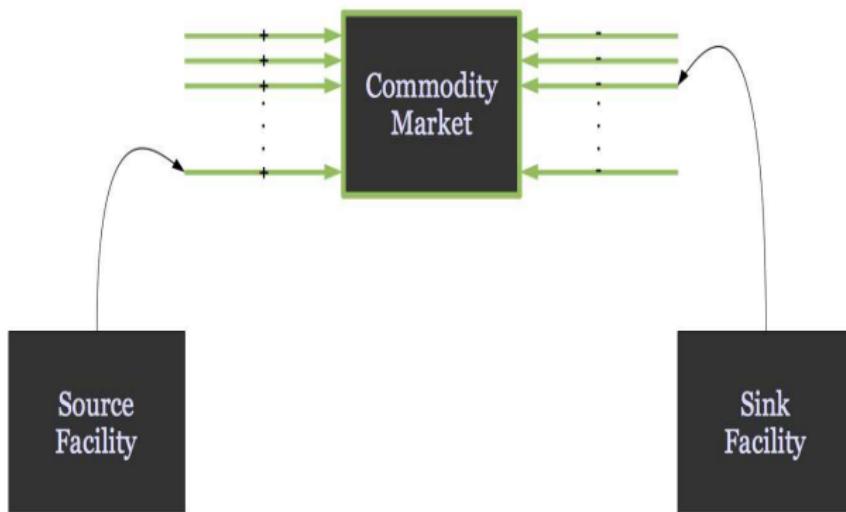

## The Market Solves the Matching Problem

**Figure:** When the Market's arbitrary algorithm solves the matching problem, the Market sends instructions to the offering facilities.

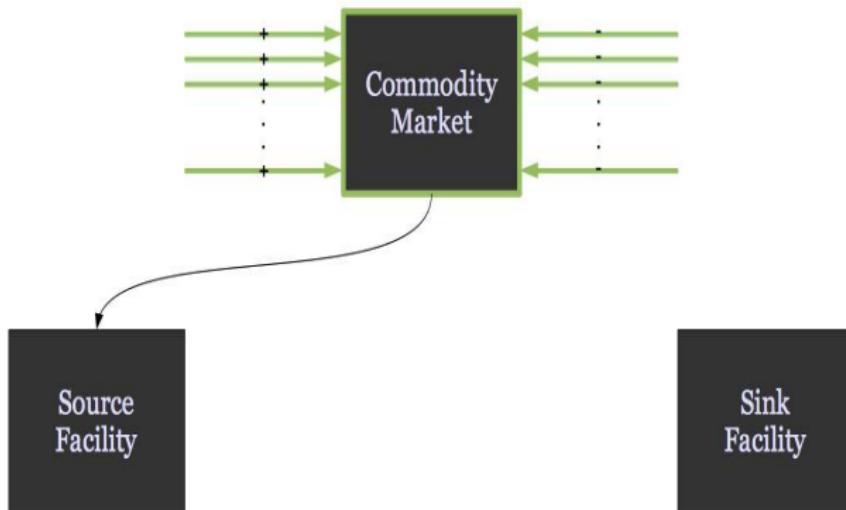

## A Simple Example

**Figure:** The source sends an offer and the sink sends a request.

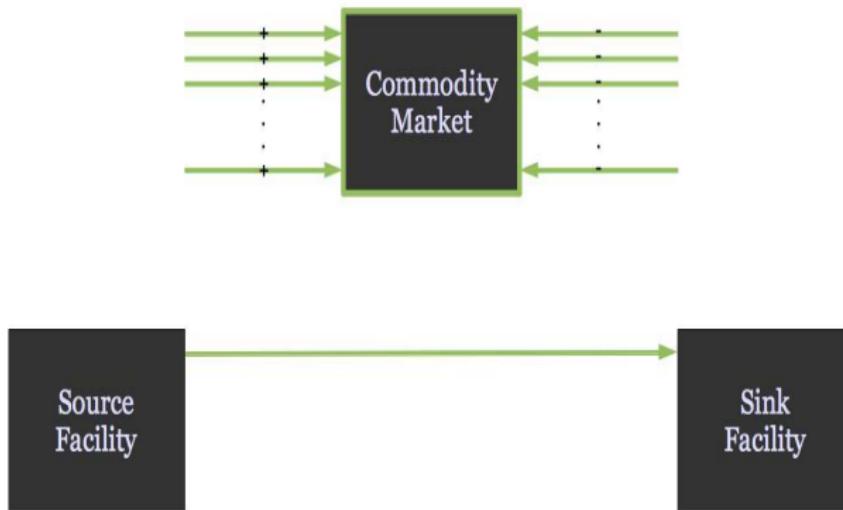

## A Simple Example

**Figure:** The Market solves the problem and instructs the source facility to send a certain amount to the sink facility.

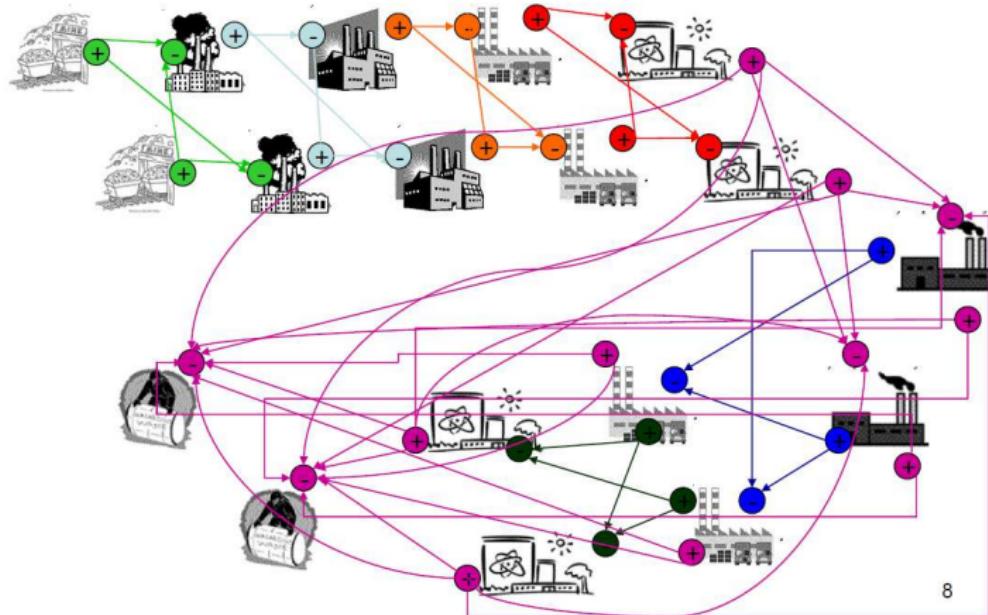

## A Simple Example

**Figure:** The source facility sends the material directly to the sink facility.

## This Market Model Scales for Complex Systems

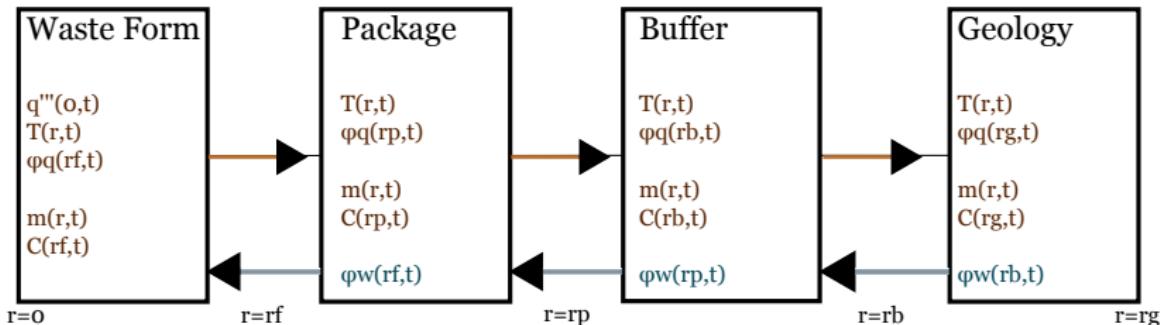

**Figure:** Well designed interfaces and strict encapsulation support scalability of the Market-based simulation paradigm [?]

## Nested Components

### Quantities Calculated Each Timestep

**Figure:** The nested components supply thermal flux and concentration information to each other at the boundaries.

Demonstration Case  
Base Case  
Extensions  
Summary

## Demonstration Case : Code Development

The demonstration case is an empty software architecture in which to implement the physical models. This demonstration will build and test

- component module loading of models and data
- information passing between modules
- and database writing.

## Demonstration Case : Dynamic Module Loading

With a dynamic, plug-in implementation, the simulation logic is independent of the available models and models are loaded as shared libraries at runtime.

	input.xml
	<pre>&lt;simulation&gt;   &lt;startYear&gt;1962&lt;/startYear&gt;   &lt;duration&gt;1200&lt;/duration&gt;   &lt;region&gt;     &lt;name&gt;UChicago&lt;/name&gt;     &lt;DeployRegionModel&gt;       &lt;deployment&gt;         &lt;facility&gt;           &lt;name&gt;ChiPile1&lt;/name&gt;           &lt;model&gt;RecipeReactor&lt;/model&gt;         &lt;/facility&gt;         &lt;year&gt;1942&lt;/year&gt;       &lt;/deployment&gt;     &lt;/DeployRegionModel&gt;   .   .   . &lt;/region&gt; &lt;/simulation&gt;</pre>

Figure: XML input parsing and a relaxNG schema provide a simplified XML interface is available for the end user to define available module implementations of models and data.

## Version Control

This open source repository employs a version control system for provenance, developer access, and reproducibility of results.

## Base Case : Component Abstraction

each component?

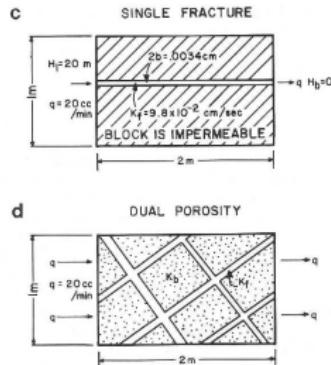

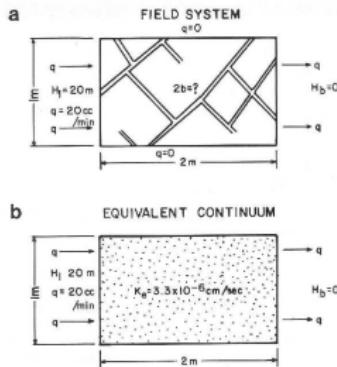

## Base Case : System Level Abstraction

tell the difference between component models.

## Extensions : Fracturation

**Fig. 12.6** Conceptual models of a fractured rock system (modified from Gale, 1982).  
 (a) A simplified fracture network of aperture  $2b$  with groundwater flow from left to right.  
 (b) Equivalent porous medium model of (a).  
 (c) Discrete fracture model of (a).  
 (d) Dual porosity medium model of (a).

A dual continuum model will be implemented to more accurately represent fractured host media such as granite [?].

## Extensions : Sorption

**Table 3** Retardation factors for important radionuclides in rock materials being considered for repository siting<sup>a</sup>

Element	$R_f = 1 + K_d \times \frac{\text{density of rock}}{\text{porosity of rock}} = \frac{\text{rate of groundwater movement}}{\text{rate of radionuclide movement}}$				
	Granite	Basalt	Tuff (volcanic ash)	Shale or clay	Salt
Sr	20–4,000	50–3,000	100–100,000	100–100,000	10–50
Cs	200–100,000	200–100,000	500–100,000	200–100,000	40–100
I	1	1	1	1	1
Tc	1–40	1–100	1–100	1–40	1–10
U	20–500	50–500	10–400	50–2,000	20–100
Np	10–500	10–200	10–200	40–1,000	10–200
Pu	20–2,000	20–10,000	50–5,000	50–100,000	40–4,000
Am	500–10,000	100–1,000	100–1,000	500–100,000	200–2,000

<sup>a</sup> The table is compiled from reported experimental values in many sources. The high figure in each range is an estimate for assumed most common repository conditions ( $Eh = -0.2$  to  $-0.3$  V,  $pH = 7$  to 9); the low figure is an estimate of the minimum value under less favorable conditions of  $Eh$ ,  $pH$ , or complexing. The numbers for salt do not refer to sorption on salt itself, but rather on ordinary rock material in the vicinity of a salt repository, where the groundwater may be fairly concentrated brine.

## Extensions : Coalescence

Salt and clay exhibit coalescent behavior under heat.
